Principles of Optical Mineralogy

Optical mineralogy involves examining thin sections of mineral samples under a petrographic microscope. Light interacts with mineral crystals, producing characteristic optical effects based on their internal structure and composition. Key optical properties used for identification include:

- Refractive index (RI): The measure of how much light bends as it passes through the mineral.
- Birefringence: The difference in RI in different crystallographic directions, leading to interference colors.
- Pleochroism: The change in color when viewed from different angles under polarized light.
- Optic sign: Whether the mineral is optically positive or negative.
- Extinction angles: The angle at which the mineral goes dark under crossed polarizers.
