Video and Audio Acquisition

This initial stage involves capturing high-quality signals using cameras and microphones. The raw signals are often in analog form, requiring conversion to digital for modern processing.

Analog-to-Digital Conversion (ADC)

ADC samples the analog signals at high rates, converting them into digital data streams that can be processed, compressed, and transmitted efficiently.

Compression Modules

Given the vast amount of data in high-definition video and audio, compression algorithms like MPEG-2 and H.264 significantly reduce data size without perceptible loss in quality. Compression is vital for efficient bandwidth utilization.

Multiplexing

This process combines multiple data streams—such as different camera angles, audio tracks, or subtitles—into a single data stream, maintaining synchronization across all components.

Error Correction Coding

Errors may occur due to noise, interference, or signal degradation. Error correction codes enable the receiver to detect and correct many types of errors, ensuring smooth playback.

Modulation and RF Transmission

Digital signals are modulated onto RF carriers suitable for the transmission medium. OFDM is commonly used in HDTV broadcasting for its robustness against multipath interference.

Reception and Demodulation

The receiver's RF front-end filters and demodulates the signals, recovering the digital data streams.

Error Correction Decoding

The decoding process identifies and corrects errors introduced during transmission, crucial for maintaining high-quality HDTV content.

Decoding and Decompression

The compressed streams are decompressed to retrieve the original high-definition video and audio data.

Display and Playback

Finally, the digital signals are converted back to analog form (if necessary) and displayed on HDTV screens, providing viewers with crisp images and immersive sound.
