2. Subatomic Particles

- Protons: Positively charged particles in the nucleus; atomic number (Z) equals the number of protons. - Neutrons: Neutral particles contributing to atomic mass. - Electrons: Negatively charged particles orbiting the nucleus; determine chemical behavior.

3. Atomic Number, Atomic Mass, and Isotopes

- Atomic Number (Z): Number of protons. - Atomic Mass Number (A): Sum of protons and neutrons. - Isotopes: Atoms with same Z but different A, e.g., Carbon-12 and Carbon-14.

4. Electron Configuration and Quantum Numbers

Understanding how electrons are distributed among orbitals: - Principal Quantum Number (n): Energy level. - Azimuthal Quantum Number (l): Subshell (s, p, d, f). - Magnetic Quantum Number (m): Orbital orientation. - Spin Quantum Number (s): Electron spin (+1/2 or -1/2). Practicing electron configuration notation helps predict chemical reactivity and bonding.

Chemical Bonding and Molecular Structure

Bonding is at the heart of chemical interactions. It explains how atoms combine to form molecules and compounds, influencing their physical and chemical properties.

1. Types of Chemical Bonds

- Ionic Bonds: Formed due to electrostatic attraction between oppositely charged ions, typically between metals and nonmetals. - Covalent Bonds: Sharing of electron pairs between nonmetals. - Coordinate Covalent Bonds: A pair of electrons donated by one atom to another.

2. Factors Affecting Bond Formation

- Electronegativity Difference: Determines bond type; large difference favors ionic bonds. - Atomic Size: Smaller atoms tend to form stronger bonds. - Bond Polarity: Results from unequal sharing of electrons, leading to dipole moments.

3. Molecular Geometry and VSEPR Theory

- Valence Shell Electron Pair Repulsion (VSEPR): Predicts molecular shapes based on electron pair repulsion. - Common Geometries: - Linear (e.g., CO_2) - Trigonal Planar (e.g., BF_3) - Tetrahedral (e.g., CH_4) - Trigonal Bipyramidal (e.g., PCl_5) - Octahedral (e.g., SF_6) Understanding molecular shapes is crucial for predicting physical properties and reactivity.

4. Hybridization

- Describes the mixing of atomic orbitals to form new hybrid orbitals. - Examples: - sp^3 (tetrahedral) - sp^2 (trigonal planar) - sp (linear)

States of Matter and Gas Laws

A thorough understanding of matter's physical states and behaviors under various conditions is essential in chemistry.

1. Solids, Liquids, Gases, and Plasma

- Solids: Fixed shape and volume, particles closely packed. - Liquids: Fixed volume, shape conforms to container. - Gases: No fixed shape or volume, particles widely spaced. - Plasma: Ionized gases, prevalent in stars and certain laboratory conditions.

Questions & Answers About intermediate 1st year chemistry

No	Question	Answer
1	What is the difference between atomic number and atomic mass?	Atomic number is the number of protons in an atom's nucleus, determining the element's identity. Atomic mass is the total mass of protons and neutrons in an atom's nucleus, representing the atom's mass in atomic mass units (amu).
2	How do isotopes of an element differ from each other?	Isotopes of an element have the same number of protons but different numbers of neutrons, resulting in different atomic masses but similar chemical properties.
3	Explain the concept of valency with an example.	Valency is the combining capacity of an element, usually determined by the number of electrons an atom can gain, lose, or share. For example, sodium (Na) has a valency of 1 because it loses one electron to achieve a stable octet.

4	What is the octet rule?	The octet rule states that atoms tend to gain, lose, or share electrons to attain a full outer shell of 8 electrons, achieving a stable electronic configuration similar to noble gases.
5	Describe the structure of an atom according to the Bohr model.	In the Bohr model, an atom consists of a small, positively charged nucleus at the center with electrons orbiting in specific circular paths or shells at fixed distances from the nucleus.
6	What is a molecule and how is it different from an atom?	A molecule is a group of two or more atoms chemically bonded together, representing the smallest unit of a compound with definite properties. An atom is a single unit of an element, not bonded to other atoms.
7	Define electronegativity and its trend in the periodic table.	Electronegativity is the tendency of an atom to attract electrons toward itself in a chemical bond. It increases across a period from left to right and decreases down a group from top to bottom.
8	What are ionic bonds and how are they formed?	Ionic bonds are electrostatic forces of attraction between oppositely charged ions, formed when one atom loses electrons to become a cation and another gains electrons to become an anion, as in the formation of sodium chloride (NaCl).
